# KY FAN INEQUALITY AND BOUNDS FOR DIFFERENCES OF MEANS II 

PENG GAO

#### Abstract

We study properties of Ky -Fan typed inequalities and their relations to certain bounds for the differences of means.

## 1. Introduction

Let $P_{n, r}(\mathbf{x})$ be the generalized weighted power means: $P_{n, r}(\mathbf{x})=\left(\sum_{i=1}^{n} \omega_{i} x_{i}^{r}\right)^{\frac{1}{r}}$, where $\omega_{i}>$ $0,1 \leq i \leq n$ with $\sum_{i=1}^{n} \omega_{i}=1$ and $\mathbf{x}=\left(x_{1}, x_{2}, \cdots, x_{n}\right)$. Here $P_{n, 0}(\mathbf{x})$ denotes the limit of $P_{n, r}(\mathbf{x})$ as $r \rightarrow 0^{+}$. Unless specified, we always assume $0 \leq x_{1} \leq x_{2} \cdots \leq x_{n}, m=\min \left\{x_{i}\right\}, M=\max \left\{x_{i}\right\}$, $r>s, q \in[0,1]$. We denote $\sigma_{n}=\sum_{i=1}^{n} \omega_{i}\left(x_{i}-A_{n}\right)^{2}$.

To any given $\mathbf{x}, t, \epsilon \geq 0$ we associate $\mathbf{x}(\epsilon)=\left(1-\epsilon x_{1}, 1-\epsilon x_{2}, \cdots, 1-\epsilon x_{n}\right), \mathbf{x}_{t}=\left(x_{1}+t, \cdots, x_{n}+t\right)$ and $\mathbf{x}^{\prime}=\mathbf{x}(1)$. When there is no risk of confusion, We shall write $P_{n, r}$ for $P_{n, r}(\mathbf{x}), P_{n, r, t}$ for $P_{n, r}\left(\mathbf{x}_{t}\right)$, $P_{n, r}^{\prime}$ for $P_{n, r}\left(\mathbf{x}^{\prime}\right)$ and $P_{n, r}(\epsilon)$ for $P_{n, r}(\mathbf{x}(\epsilon))$ if $1-\epsilon x_{i} \geq 0$ for all $i$. We also define $A_{n}=P_{n, 1}, G_{n}=$ $P_{n, 0}, H_{n}=P_{n,-1}$ and similarly for $A_{n, t}, G_{n, t}, H_{n, t}, A_{n}(\epsilon), G_{n}(\epsilon), H_{n}(\epsilon), A_{n}^{\prime}, G_{n}^{\prime}, H_{n}^{\prime}$.

Let $m>0$, we consider the following bounds for the differences between power means:

$$
\begin{equation*}
\frac{r-s}{2 m} \sigma_{n} \geq P_{n, r}-P_{n, s} \geq \frac{r-s}{2 M} \sigma_{n} \tag{1.1}
\end{equation*}
$$

We will refer to (1.1) as $I_{r, s, n}$. D.Cartwright and M.Field 6 first proved the validity of $I_{1,0, n}$, a refinement of the arithmetic-geometric mean inequality. For other extensions and refinements of (1.1), see [3], 8] and [10]. We note the constant $(r-s) / 2$ is best possible.

There is a close relation between (1.1) and the following additive Ky Fan's inequality ( $m<M<$ 1):

$$
\begin{equation*}
\frac{m}{1-m}<\frac{P_{n, r}^{\prime}-P_{n, s}^{\prime}}{P_{n, r}-P_{n, s}}<\frac{M}{1-M} \tag{1.2}
\end{equation*}
$$

The case $r=1, s=0, x_{n} \leq 1 / 2$ in $(1.2)$ is due to H. Alzer 4. P. Mercer 12 showed Alzer's result follows from the result of Cartwright and Field. Recently, the author 9 showed that (1.1) and (1.2) are equivalent. We refer the reader to the survey article 2 and the references therein for an account of Ky Fan's inequality.

It is an open problem to determine all the pairs $(r, s)$ so that $I_{r, s, n}$ is valid for all $n$. It is natural to try to reduce the problem to the case $n=2$. In this paper, we will reduce the problem to the case $n=3$ and in many situations $n=2$.

A counterpart of $(1.2)$ is the following result of J.Aczél and Zs. Pâles $[1]$ ( " $\geq$ " for $s<1$, " $\leq$ " for $s>1$ ):

$$
\begin{equation*}
P_{n, s, t}-A_{n, t} \geq(\leq) P_{n, s}-A_{n} \tag{1.3}
\end{equation*}
$$

J.Brenner and B. Carlson 5 studied the asymptotic behavior of $t\left(P_{n, r, t}-A_{n, t}\right)$ and showed it is bounded. As an analogue to the relation between (1.1) and 1.2 , we shall establish an equivalent relation between (1.1) and inequalities similar to (1.3) in this paper. We will also discuss certain asymptotic behaviors of the differences of means.

[^0]
## 2. The Main Theorem

Lemma 2.1. If $I_{r, s, n}$ holds, then $0 \leq r+s \leq 3$ and $q^{1 / r}-q^{1 / s} \geq(r-s) q(1-q) / 2$ for $s>0$, $q^{1 / r} \geq(r-s) q(1-q) / 2$ for $s \leq 0$. In particular, $r \geq 1, r s \leq 2$ and $r$ is bounded above.

Proof. The condition $0 \leq r+s \leq 3$ was proved in 9. Now let $n=2$, write $\omega_{1}=1-q, \omega_{2}=q$, $x_{1}=1$ and $x_{2}=1+t$ with $t \geq-1$. Let

$$
\begin{equation*}
D(t ; r, s, q)=\frac{r-s}{2} \sigma_{2}-P_{2, r}+P_{2, s} \tag{2.1}
\end{equation*}
$$

For $t \geq 0, D(t ; r, s, q) \geq 0$ implies the validity of the left-hand side inequality of (1.1) while for $-1 \leq t \leq 0, D(t ; r, s, q) \leq 0$ implies the validity of the right-hand side inequality of (1.1).

By taking $t \rightarrow-1$ in (2.1) we get $q^{1 / r}-q^{1 / s} \geq(r-s) q(1-q) / 2$ for $s>0$ and $q^{1 / r} \geq(r-s) q(1-q) / 2$ for $s \leq 0$. By letting $q \rightarrow 0$ in each case implies $r \geq 1$ (note $r>0$ because of $r+s \geq 0$ ). By letting $q \rightarrow 1$ when $s>0$ gives $r s \leq 2$. Furthermore, $r+s \leq 3$ implies $r-s \geq 2 r-3$. This then implies for $s \leq 0, q^{1 / r} \geq(2 r-3) q(1-q) / 2$, which fails to hold when $r \rightarrow \infty$ for a fixed $q \neq 0$. Thus $r$ is bounded above and this completes the lemma.

Lemma 2.1 allows us to focus on $0 \leq r+s \leq 3, r \geq 1$ when considering the validities of (1.1).
Lemma 2.2. For $2>r>s>1,0 \leq x_{i} \leq 1$

$$
\begin{equation*}
P_{n, r}^{1-r} \geq P_{n, s}^{1-s} \tag{2.2}
\end{equation*}
$$

Proof. This is equivalent to

$$
\left(1-\frac{1}{r}\right) \ln \left(\sum_{i=1}^{n} \omega_{i} x_{i}^{r}\right)^{-1} \geq\left(1-\frac{1}{s}\right) \ln \left(\sum_{i=1}^{n} \omega_{i} x_{i}^{s}\right)^{-1}
$$

and the above inequality holds since $1-\frac{1}{r}>1-\frac{1}{s}>0$ and $\left(\sum_{i=1}^{n} \omega_{i} x_{i}^{r}\right)^{-1} \geq\left(\sum_{i=1}^{n} \omega_{i} x_{i}^{S}\right)^{-1} \geq 1$.
Lemma 2.3. $I_{r, s, n}$ holds for all $n$ if and only if $I_{r, s, 3}$ holds.
Proof. We will prove the lemma for the left-hand side inequality of 1.1 and the proof for the right-hand side inequality of $(1.1)$ is similar. We may assume $x_{1}=1<x_{n}=b, x_{i} \in(1, b)$ and define two functions $\left(\omega=\left(\omega_{1}, \omega_{2}, \cdots, \omega_{n}\right)\right)$ :

$$
\begin{aligned}
f(\omega, \mathbf{x}) & =x_{1}\left(P_{n, r}-P_{n, s}\right)-\frac{r-s}{2} \sigma_{n} \\
g(x) & =x_{1}\left(P_{n, r}^{1-r} x^{r} / r-P_{n, s}^{1-s} x^{s} / s\right)-(r-s)\left(x^{2}-2 x A_{n}\right) / 2-\lambda
\end{aligned}
$$

where we define $x^{0} / 0$ to be $\ln x$. Note here in the definition of $g(x), P_{n, r}, P_{n, s}, A_{n}$ are not functions of $x$, they take values at some points $(\omega, \mathbf{x})$ to be specified and $\lambda$ is also a constant to be specified.

We prove the lemma by induction on $n$. It suffices to show $f(\omega, \mathbf{x}) \leq 0$ on the region $R_{n} \times S_{n-2}$, where $R_{n}=\left\{\left(\omega_{1}, \omega_{2}, \cdots, w_{n}\right): 0 \leq w_{k} \leq 1,1 \leq k \leq n, \sum_{k=1}^{n} w_{k}=1\right\}$ and $S_{n-2}=\left\{\left(x_{2}, \cdots, x_{n-1}\right)\right.$ : $\left.x_{k} \in[1, b], 2 \leq k \leq n-1\right\}$. It suffices to show $f$ takes its minimal value at $n \leq 3$. The base case of $n \leq 3$ is clear. Now assume $n \geq 4$.

There is a point $\left(\omega^{\prime}, \mathbf{x}^{\prime}\right)$ of $R_{n} \times S_{n-2}$ where $f$ is minimized subject to the constraint $\sum_{k=1}^{n} \omega_{k}=1$. If $x_{i}^{\prime}=x_{i+1}^{\prime}$ for some $1 \leq i \leq n-1$, by combining $x_{i}^{\prime}$ with $x_{i+1}^{\prime}$ and $\omega_{i}^{\prime}$ with $\omega_{i+1}^{\prime}$, we are back to the case of $n-1$ variables with different weights. Similarly, if $\omega_{i}^{\prime}=1$ for some $i$ then we are back to the case $n=1$. If $\omega_{i}^{\prime}=0$ for some $i>1$, we are back to the case $n-1$. If $\omega_{1}^{\prime}=0$, since

$$
x_{2}^{\prime}\left(P_{n-1, r}-P_{n-1, s}\right)-\frac{r-s}{2} \sigma_{n-1} \geq x_{1}^{\prime}\left(P_{n, r}-P_{n, s}\right)-\frac{r-s}{2} \sigma_{n}
$$

we are again back to the case $n-1$. So without loss of generality, from now on we may assume for $1 \leq i, j \leq n, i \neq j, \omega_{i} \neq 0,1, x_{i} \neq x_{j}$ and this implies $\left(\omega^{\prime}, \mathbf{x}^{\prime}\right)$ is an interior point of $R_{n} \times S_{n-2}$.

Thus we may use the Lagrange multiplier method to obtain a real number $\lambda$ so that at $\left(\omega^{\prime}, \mathbf{x}^{\prime}\right)$ :

$$
\begin{equation*}
\frac{\partial f}{\partial w_{i}}=\lambda \frac{\partial}{\partial \omega_{i}}\left(\sum_{k=1}^{n} w_{k}-1\right), \frac{1}{\omega_{j}} \frac{\partial f}{\partial x_{j}}=0 \tag{2.3}
\end{equation*}
$$

for all $1 \leq i \leq n$ and $2 \leq j \leq n-1$.
By (2.3), a computation shows each $x_{k}^{\prime}(2 \leq k \leq n-1)$ is a common root of the equations $g(x)$ and $g^{\prime}(x)$ (where $P_{n, r}$ takes its value at $\left(\omega^{\prime}, \mathbf{x}^{\prime}\right)$, etc.). Now $n \geq 4$ implies $g(x)$ and $g^{\prime}(x)$ have in common at least two distinct, positive roots, $1<x_{2}^{\prime}, x_{3}^{\prime}<b$. Moreover, $g(1)=g(b)=0$ by (2.3) and it follows from Rolle's Theorem that there must be at least five positive roots of $g^{\prime}(x)$ and thus at least three positive roots of $g^{\prime \prime \prime}(x)$. But

$$
g^{\prime \prime \prime}(x)=(r-1)(r-2) P_{n, r}^{1-r} x^{r-3}-(s-1)(s-2) P_{n, s}^{1-s} x^{s-3}
$$

has at most one positive root and this contradiction implies the lemma.
Theorem 2.1. For $r \geq 1,3 \geq r+s \geq 0$, except possibly for the left-hand side inequality of (1.1) when $r>2$, (1.1) holds for all $n$ if and only if it holds for $n=2$.

Proof. To facilitate the discussion, we will assume without loss of generality that for the left-hand side inequality of (1.1), $x_{1}=1$ and $x_{i} \geq 1,2 \leq i \leq n$. For the right-hand side of (1.1), $x_{1}=1$ and $0 \leq x_{i} \leq 1,2 \leq i \leq n$. The functions $f, g$ used in the proof are defined as in Lemma 2.3 .

We consider the right-hand side inequality of (1.1) first. Here we write $\mathbf{x}_{m, t}=\left(1, \cdots, x_{m}, t, \cdots, t\right)$ for some $m \leq n-1, x_{i}>0,1 \leq i \leq m$ and define $f\left(\omega, \mathbf{x}_{m, 0}\right)$ to be $\lim _{t \rightarrow 0} f\left(\omega, \mathbf{x}_{m, t}\right)$. One checks that this makes $f$ continuous on the boundary of $R_{n} \times S_{n-1}^{\prime}$ and differentiable in the interior part of $R_{n} \times S_{n-1}^{\prime}$, where $R_{n}$ is defined as in the proof of Lemma 2.3 and $S_{n-1}^{\prime}=\left\{\left(x_{2}, \cdots, x_{n}\right): x_{k} \in\right.$ $[0,1], 2 \leq k \leq n\}$.

As in the proof of Lemma 2.3 , we may assume for $1 \leq i, j \leq n, i \neq j, \omega_{i} \neq 0,1, x_{i} \neq x_{j}$. It also follows from the proof of Lemma 2.3 and the definition of $f\left(\omega, \mathbf{x}_{m, 0}\right)$ that it suffices to show $f \geq 0$ with $n=3, x_{3}=0$. If $s \leq 0$, this becomes $P_{3, r}-\frac{r-s}{2} \sigma_{3} \geq 0$ and one using the method in the proof of Lemma 2.3 can easily show that $P_{n, r}-\frac{r-s}{2} \sigma_{n} \geq 0$ holds if and only if it holds for $n=2$. Since $P_{2, r}-\frac{r-s}{2} \geq P_{2, r}-P_{2, s}-\frac{r-s}{2}$, this shows that we only need to check $I_{r, s, 2}$.

Now we let $s>0$. If $1 \leq r \leq 2, s \leq 1, g^{\prime \prime \prime}(x)$ has no positive root and by similar arguments as in the proof of Lemma 2.3, it suffices to check $I_{r, s, 2}$. For $2<r \leq 3, s<1$, it suffices to check $I_{r, s, 3}$ with $x_{3}=0$ by similar reasons as above. We allow $x_{1} \leq 1$ here and $f$ is defined on $R_{3} \times[0,1]^{3}$. Suppose $f$ takes its absolute minimum at $1 \geq x_{1}>x_{2}>x_{3}=0$, one checks in this case $\lim _{x \rightarrow 0} g^{\prime}(x)=-\infty$. Also from the proof of Lemma 2.3 , we know $g^{\prime}(x)$ has exactly three positive roots, all less than $x_{1}$. If this really is the case then we can deduce that $g^{\prime}\left(x_{1}\right)>0$ and

$$
\frac{\partial f}{\partial x_{1}}=g^{\prime}\left(x_{1}\right)+P_{n, r}-P_{n, s}>0
$$

which implies by decreasing $x_{1}$ while fixing $x_{3}=0$ and $x_{2}$, we can decrease the value of $f$, a contradiction. Thus it also suffices to check $I_{r, s, 2}$ in this case.

Similarly, when $1<s<r<2, n=3, g^{\prime \prime}(x)$ has exactly two positive roots, both less than 1 , since $\lim _{x \rightarrow 0} g^{\prime \prime}(x)<0$, we must have $g^{\prime \prime}(1)<0$, however by lemma 2.2 ,

$$
g^{\prime \prime}(1)=(r-1)\left(P_{n, r}^{1-r}-1\right)-(s-1)\left(P_{n, s}^{1-s}-1\right) \geq 0
$$

a contradiction, so it also suffices to check $I_{r, s, 2}$ in this case.
Now for the left-hand side inequality of 1.1), we may also assume for $1 \leq i, j \leq n, i \neq j$, $\omega_{i} \neq 0,1, x_{i} \neq x_{j}$. In this case, it suffices to show $f \leq 0$.

If $1 \leq r \leq 2, s \leq 1, g^{\prime \prime \prime}(x)$ has no positive root and it suffices to check $I_{r, s, 2}$. If $1<s<r<2$, we allow $1 \leq x_{1} \leq x_{2} \leq x_{3} \leq b$ in this case and $f$ is defined on $R_{3} \times[1, b]^{3}$. Suppose $f$ takes its absolute minimum at $1 \leq x_{1}<x_{2}<x_{3}=b$, one checks in this case $g^{\prime}(x)$ has exactly three positive
roots, all lie in $\left(x_{1}, b\right)$. Since $\lim _{x \rightarrow \infty} g^{\prime}(x)<0$, if $g^{\prime}(b)>0, g^{\prime}(x)$ will have another root in $(b,+\infty)$, contradicting the fact $g^{\prime \prime \prime}(x)$ only has one positive root. Thus $g^{\prime}(b)<0$, which implies $g^{\prime}\left(x_{1}\right)>0$. But

$$
\frac{\partial f}{\partial x_{1}}=g^{\prime}\left(x_{1}\right)+P_{n, r}-P_{n, s}>0
$$

which implies by increasing $x_{1}$ while fixing $x_{2}, x_{3}$, we can increase the value of $f$, a contradiction. Thus it also suffices to check $I_{r, s, 2}$ in this case.

Corollary 2.1. Let $0 \leq r+s \leq 3$. If $1 \leq r \leq 2, s \leq 1$, $I_{r, s, n}$ holds. For $r>2,1 / 2 \leq s<1$, the right-hand side inequality of (1.1) holds. In all the cases the equality holds if and only if $x_{1}=x_{2}=\cdots=x_{n}$.
Proof. The case $1 \leq r \leq 2, s \leq 1$ is a result of the author 9 , we leave the proof to the reader since it is similar to the one we will give below. We note the condition for equality is given here while it was missing in 9 .

For the case $r>2,1 / 2 \leq s<1$, it suffices to prove the case $n=2$ by Theorem 2.1. Let $x_{1}=x, x_{2}=1, \omega_{1}=q, \omega_{2}=1-q$ and we rewrite $I_{r, s, 2}$ as

$$
F(x)=\left(q x^{r}+1-q\right)^{1 / r}-\left(q x^{s}+1-q\right)^{1 / s}-\frac{(r-s) q(1-q)}{2}(x-1)^{2}
$$

We need to show $F(x) \geq 0$ for $0 \leq x \leq 1$. We may also assume $q \neq 0,1$ and calculation yields

$$
\begin{equation*}
(q(1-q))^{-1} F^{\prime \prime}(x)=(r-1)\left(q x^{r}+1-q\right)^{\frac{1-2 r}{r}} x^{r-2}+(1-s)\left(q x^{s}+1-q\right)^{\frac{1-2 s}{s}} x^{s-2}-(r-s) \tag{2.4}
\end{equation*}
$$

We define $H(q)$ to be the right-hand side expression in (2.4). Now for $r>2,1 / 2 \leq s<1$,

$$
\begin{aligned}
H^{\prime}(q)= & (r-1)(1-2 r)\left(q+(1-q) x^{-r}\right)^{\frac{1-3 r}{r}} x^{-r-1} \frac{1-x^{-r}}{r} \\
& -(s-1)(1-2 s)\left(q+(1-q) x^{-s}\right)^{\frac{1-3 s}{s}} x^{-s-1} \frac{1-x^{-s}}{s} \geq 0
\end{aligned}
$$

Thus $H(q) \geq H(0)=(r-1) x^{r-2}-(s-1) x^{s-2}-(r-s):=h(x)$. By setting $h^{\prime}(x)=0$ we get $x^{r-s}=\frac{(1-s)(2-s)}{(1-r)(2-r)} \geq 1$, since the last inequality is equivalent to $(r+s-3)(r-s) \leq 0$. Thus $h(x) \geq \min \left\{h(1), \lim _{x \rightarrow 0} h(0)\right\}=0$.

Thus $F^{\prime \prime}(x) \geq 0$ for $x \leq 1$ and $F(x) \geq 0$ for $x \in[0,1]$ follows by considering the Taylor expansion of $F(x)$ at $x=1$ with the observation $F(1)=F^{\prime}(1)=0$. It is also easy to see that the equality holds if and only if $x_{1}=\cdots=x_{n}$ and this completes the proof.

## 3. Relations Among Ky-Fan typed Inequalities

Let $n \geq 2,0<x_{1}<x_{n}$, consider the following inequalities:

$$
\begin{equation*}
D\left(x_{1}\right) \sigma_{n}>P_{n, r}-P_{n, s}>D\left(x_{n}\right) \sigma_{n} \tag{3.1}
\end{equation*}
$$

where

$$
D(t)=\frac{\left(P_{n, r} / t\right)^{1-r}-\left(P_{n, s} / t\right)^{1-s}}{2\left(t-A_{n}\right)}
$$

The case $r=1, s=0$ in (3.1) is a result of A. Mercer 11 and the author 8 proved (3.1) for $r=1,0<s<1$. It is easy to see that in those cases (3.1) refine (1.1).

We note here $D\left(x_{1}\right), D\left(x_{n}\right) \geq 0$ but $D\left(x_{1}\right) \geq D\left(x_{n}\right)$ does not hold in general. For example, when $r>s>1$, the choice $n=2, x_{1}=0, x_{2}=1, \omega_{1} \neq 0,1$ leads to $D\left(x_{2}\right)>D\left(x_{1}\right)=0$. The same reason shows (3.1) does not always hold. Nor does (3.1) in general give refinements of (1.1). For example, if $D\left(x_{n}\right) \geq(r-s)\left(2 x_{n}\right)^{-1}$, the choice $s>0, n=2, x_{1}=0, x_{2}=1, \omega_{1}=q \rightarrow 0$ will lead to $r s \leq 1$ which shows $D\left(x_{n}\right) \geq(r-s)\left(2 x_{n}\right)^{-1}$ does not hold for $r=2, s=1$. It is interesting to know whether certain lower bounds(respectively, upper bounds) for the differences of means will imply certain upper bounds(respectively,lower bounds) for the differences. By using (3.1), we have:

Proposition 3.1. Let $n \geq 2,0<x_{1}<x_{n}$. If either side of (3.1) inequality holds, then the opposite side inequality of (1.1) holds.

Proof. We will show the left-hand side inequality of (1.1) follows from the right-hand side inequality of (3.1) and the other proof is similar. consider

$$
f(\mathbf{x})=\left(P_{n, r}-P_{n, s}\right) / \sigma_{n}
$$

then by our assumption

$$
\frac{\sigma_{n}^{2}}{\omega_{n}} \frac{\partial f}{\partial x_{n}}=\left(\left(P_{n, r} / x_{n}\right)^{1-r}-\left(P_{n, s} / x_{n}\right)^{1-s}\right) \sigma_{n}-2\left(P_{n, r}-P_{n, s}\right)\left(x_{n}-A_{n}\right)<0
$$

Thus by letting $x_{n}$ tend to $x_{n-1}, x_{n-1}$ tend to $x_{n-2}$ and noticing

$$
\lim _{x_{2} \rightarrow x_{1}}\left(P_{2, r}-P_{2, s}\right) / \sigma_{2}=(r-s) /\left(2 x_{1}\right)
$$

We get

$$
\left(P_{n, r}-P_{n, s}\right) / \sigma_{n} \leq(r-s) /\left(2 x_{1}\right)
$$

which is the desired conclusion.
We note here from the proof of Proposition 3.1, if one assumes $P_{n, r}-P_{n, s}<D\left(x_{n}\right) \sigma_{n}$ instead, one will get $P_{n, r}-P_{n, s} \geq(r-s) \sigma_{n} /\left(2 x_{1}\right)$.

We now consider a general form of (1.1) $(\alpha \leq 2)$ :

$$
\begin{equation*}
\frac{r-s}{2 m^{2-\alpha}} \sigma_{n} \geq \frac{P_{n, r}^{\alpha}-P_{n, s}^{\alpha}}{\alpha} \geq \frac{r-s}{2 M^{2-\alpha}} \sigma_{n} \tag{3.2}
\end{equation*}
$$

where we define $\left(P_{n, u}^{0}-P_{n, v}^{0}\right) / 0=\ln \left(P_{n, u} / P_{n, v}\right)$, the limit of $\left(P_{n, u}^{\alpha}-P_{n, v}^{\alpha}\right) / \alpha$ as $\alpha \rightarrow 0$. We will refer to (3.2) as $I_{r, s, \alpha, n}$ (so $\left.I_{r, s, 1, n}=I_{r, s, n}\right)$. We note in 9, the following theorem was proved:
Theorem 3.1. For $x_{1}>0, q=\min \left\{\omega_{i}\right\}$

$$
\begin{align*}
& \frac{1-2 q}{2 x_{1}^{2}} \sigma_{n} \geq(1-q) \ln A_{n}+q \ln H_{n}-\ln G_{n} \geq \frac{1-2 q}{2 x_{n}^{2}} \sigma_{n}  \tag{3.3}\\
& \frac{1-2 q}{2 x_{1}^{2}} \sigma_{n} \geq \ln G_{n}-q \ln A_{n}-(1-q) \ln H_{n} \geq \frac{1-2 q}{2 x_{n}^{2}} \sigma_{n} \tag{3.4}
\end{align*}
$$

with equality holding if and only if $q=1 / 2$ or $x_{1}=\cdots=x_{n}$.
Note the right-hand side inequality of 3.3 is equivalent to

$$
(1-q)\left(\ln A_{n}-\ln G_{n}-\frac{1}{2 x_{n}^{2}} \sigma_{n}\right)-q\left(\ln G_{n}-\ln H_{n}-\frac{1}{2 x_{n}^{2}} \sigma_{n}\right) \geq 0
$$

From this we deduce
Corollary 3.1. $I_{1,0,0, n}$ is equivalent to $I_{0,-1,0, n}$.
In fact, if we assume that $I_{r, s, \alpha, n}$ holds if and only if $I_{r, s, \alpha, 2}$ holds, we then have
Proposition 3.2. If $I_{r, s, \alpha, n}$ holds if and only if $I_{r, s, \alpha, 2}$ holds, then $I_{r, s, 0, n}$ is equivalent to $I_{-s,-r, 0, n}$ and (3.3) is equivalent to (3.4).

Proof. A change of variables $x_{1} \rightarrow 1 / x_{2}, x_{2} \rightarrow 1 / x_{1}$ when $n=2$ yields the desired conclusion.
We remark here the following result of J. Chen and Z.Wang 7 is also invariant under the change $(r, s) \rightarrow(-s,-r)$ :
Theorem 3.2. For arbitrary $n, r>s, x_{i} \in(0,1 / 2], P_{n, r}^{\prime} / P_{n, s}^{\prime} \leq P_{n, r} / P_{n, s}$ holds if and only if $|r+s| \leq 3,2^{s} / s \geq 2^{r} / r$ when $s>0, s 2^{s} \leq r 2^{r}$ when $r<0$.

## 4. An Equivalence Relation

Proposition 4.1. For $t \geq 0,1.1$ is equivalent to

$$
\begin{equation*}
\frac{x_{1}}{t+x_{n}} \leq \frac{P_{n, r, t}-P_{n, s, t}}{P_{n, r}-P_{n, s}} \leq \frac{x_{n}}{t+x_{1}} \tag{4.1}
\end{equation*}
$$

Proof. The argument is similar to the one in 9 and we leave it to the reader.
By Corollary 2.1, 4.1 holds for $\mathrm{r}=1, \mathrm{~s}=0$ and now we give a refinement of this case:
Proposition 4.2. For $t \geq 0, n \geq 2, x_{1}<x_{n}$

$$
\begin{equation*}
\frac{x_{1}}{t+x_{1}} \leq \frac{A_{n, t}-G_{n, t}}{A_{n}-G_{n}} \leq \frac{x_{n}}{t+x_{n}} \tag{4.2}
\end{equation*}
$$

with equality holding if and only if $t=0$.
Proof. We will prove the left-hand side inequality of 4.2 and the proof for right-hand side inequality is similar. Let

$$
\begin{equation*}
D_{n}(\mathbf{x})=x_{n}\left(A_{n}-G_{n}\right)-\left(t+x_{n}\right)\left(A_{n, t}-G_{n, t}\right) \tag{4.3}
\end{equation*}
$$

We want to show $D_{n} \geq 0$ here. We can assume $0 \leq x_{1}<x_{2}<\cdots<x_{n}$ and prove by induction, the case $n=1$ is clear so we will start with $n>1$ variables assuming the inequality holds for $n-1$ variables. Then

$$
\frac{\partial D_{n}}{\partial x_{n}}=\left(1+\omega_{n}\right)\left[\left(A_{n}-G_{n}\right)-\left(A_{n, t}-G_{n, t}\right)\right] \geq 0
$$

where the last inequality follows from 1.3 . Thus $\frac{\partial D_{n}}{\partial x_{n}} \geq 0$ and by letting $x_{n}$ tend to $x_{n-1}$, we have $D_{n} \geq D_{n-1}$ (with weights $\left.\omega_{1}, \cdots, \omega_{n-2}, \omega_{n-1}+\omega_{n}\right)$ and thus the right-hand side inequality of (4.3) holds by induction. Since $n \geq 2$ here, it is easy to see the equality holds if and only if $t=0$.

We note here (4.2) gives a refinement of 1.3 for $r=1, s=0$. In fact it implies $f(t)=$ $\left(t+x_{n}\right)\left(A_{n, t}-G_{n, t}\right)$ is a decreasing function of $t$ while $g(t)=\left(t+x_{1}\right)\left(A_{n, t}-G_{n, t}\right)$ is an increasing function of $t$. Thus $f^{\prime}(0) \leq 0, g^{\prime}(0) \geq 0$ and we get

$$
\begin{equation*}
\frac{x_{1}}{H_{n}}\left(G_{n}-H_{n}\right) \leq A_{n}-G_{n} \leq \frac{x_{n}}{H_{n}}\left(G_{n}-H_{n}\right) \tag{4.4}
\end{equation*}
$$

By using the left-hand side inequalities of (1.1) and (4.4), we obtain a refinement of a result of A. Mercer 10]:

$$
\begin{equation*}
G_{n}-H_{n} \leq \frac{H_{n}}{2 x_{1}^{2}} \sigma_{n} \tag{4.5}
\end{equation*}
$$

It is not hard to show $t\left(P_{n, r, t}-P_{n, s, t}\right) \rightarrow(r-s) \sigma_{n} / 2$ as $t \rightarrow \infty$. We can consider higher orders of the behavior, for example

$$
\begin{aligned}
& -\lim _{t \rightarrow \infty} t\left[\left(t+x_{n}\right)\left(P_{n, r, t}-P_{n, s, t}\right)-(r-s) \sigma_{n} / 2\right]=\lim _{\epsilon \rightarrow 0}\left[\frac{\left(1-\epsilon x_{n}\right)\left(P_{n, r}(\epsilon)-P_{n, s}(\epsilon)\right)}{\epsilon^{3}}-\frac{(r-s) \sigma_{n}}{2 \epsilon}\right] \\
(4.6) & =\frac{r-s}{6}\left[(3-2 r-2 s) A_{n}^{3}+3(r+s-2) A_{n} P_{n, 2}^{2}+(3-r-s) P_{n, 3}^{3}-3 x_{n} \sigma_{n}\right]:=E(\mathbf{x})
\end{aligned}
$$

Proposition 4.3. For $0 \leq r+s \leq 3, E(\mathbf{x}) \leq 0$ with equality holding if and only if $x_{1}=\cdots=x_{n}$.
Proof. We may assume $x_{n}=1$ and $0 \leq x_{i} \leq 1$. We leave for the reader to check by applying the method in the proof of Theorem 2.1, it suffices to prove (4.6) for $n=2$. By setting $\omega_{1}=q, \omega_{2}=$ $1-q, x_{1}=x, x_{2}=1$, we rewrite (4.6) as

$$
\begin{aligned}
f(x)= & (3-2 r-2 s)(q x+1-q)^{3}+3(r+s-2)(q x+1-q)\left(q x^{2}+1-q\right) \\
& +(3-r-s)\left(q x^{3}+1-q\right)-3 q(1-q)(x-1)^{2}
\end{aligned}
$$

One verifies that $f(1)=f^{\prime}(1)=f^{\prime \prime}(1)=0$ and

$$
(6 q)^{-1} f^{\prime \prime \prime}(x)=(3-2 r-2 s) q^{2}+3(r+s-2) q+(3-r-s):=g(q)
$$

If $r+s=0$ or 3 , one checks directly $f^{\prime \prime \prime}(x) \geq 0$. For $0<r+s<3$, if $g^{\prime}(q)=0$ has no root in $[0,1]$, then $g(q) \geq \min \{g(0), g(1)\}=0$ for $0 \leq q \leq 1$. Otherwise let $q_{0}$ be the only root of $g^{\prime}(q)$ in $[0,1]$. Notice $g^{\prime}(1)=-(r+s)<0$ and $g(0)=3-r-s>0, g(1)=0$. These imply $q_{0}$ is a local maximum point of $g(q)$. So again $g(q) \geq \min \{g(0), g(1)\}=0$ for $0 \leq q \leq 1$. Now $f(x) \leq 0$ follows by considering the Taylor expansion of $f(x)$ at $x=1$. It is also easy to see that the equality holds if and only if $x_{1}=\cdots=x_{n}$ and this completes the proof.

We remark here by (1.3), $A_{n}-P_{n, s} \geq A_{n, t}-P_{n, s, t}$ hold for all $s \leq 1$. On the other hand, for $0<x_{1}, x_{n} \leq 1 / 2$, a result of the author 9 shows $A_{n}-P_{n, s} \geq A_{n}^{\prime}-P_{n, s}^{\prime}$ holds for $-1 \leq s<1$. Now for $s<0$, let $n=2, x_{1} \rightarrow 0, x_{2}=1 / 2, \omega_{1}=1-q, \omega_{2}=q$ and then let $q \rightarrow 0$, we get $1-s \geq 2^{-s}$, which shows $A_{n}-P_{n, s} \geq A_{n}^{\prime}-P_{n, s}^{\prime}$ holds if and only if $-1 \leq s<1$. Similarly, by letting $q \rightarrow 1$, we know $P_{n, r}-A_{n} \geq P_{n, r}^{\prime}-A_{n}^{\prime}$ holds if and only if $1<r \leq 2$.
